Questions?

To-do Today

1. Interpretation of linear model output in R
[See the [Rmd demo](#)]
2. SE of the regression line
3. Prediction Interval
4. Bayesian statistics
5. Practice problems

SE of the regression line

Note: $\text{Cov}(aX + bY, cW + dV) = ac\text{Cov}(X, W) + ad\text{Cov}(X, V) + bc\text{Cov}(Y, W) + bd\text{Cov}(Y, V)$

Lemma: $\text{Cov}(\bar{y}, \hat{\beta}_1) = \text{Cov}(\hat{\beta}_0 + \hat{\beta}_1 \bar{x}, \hat{\beta}_1) = \text{Cov}(\hat{\beta}_0, \hat{\beta}_1) + \bar{x}\text{Var}(\hat{\beta}_1)$

$$= -\frac{\sigma^2 \bar{x}}{n\text{Var}(x)} + \frac{\sigma^2 \bar{x}}{n\text{Var}(x)} = 0$$

$$\hat{y}_i = \bar{y} + \hat{\beta}_1(x_i - \bar{x})$$

$$\begin{aligned}\Rightarrow \text{Var}(\hat{y}_i) &= \text{Var}(\bar{y} + \hat{\beta}_1(x_i - \bar{x})) \\ &= \text{Var}(\bar{y}) + (x_i - \bar{x})^2 \text{Var}(\hat{\beta}_1) + 2(x_i - \bar{x})\text{Cov}(\bar{y}, \hat{\beta}_1) \\ &= \text{Var}(\bar{y}) + (x_i - \bar{x})^2 \text{Var}(\hat{\beta}_1) = \sigma^2 \left(\frac{1}{n} + \frac{(x_i - \bar{x})^2}{n\text{Var}(x)} \right)\end{aligned}$$

$$\Rightarrow \hat{y} \sim N(\beta_0 + \beta_1 x, \sigma^2 \left(\frac{1}{n} + \frac{(x - \bar{x})^2}{n\text{Var}(x)} \right))$$

Standard error: $s_{\hat{y}} = \hat{\sigma}^2 \left(\frac{1}{n} + \frac{(x - \bar{x})^2}{n\text{Var}(x)} \right)$

Prediction interval

$$\begin{aligned}\hat{y}_{n+1} &= \hat{\beta}_0 + \hat{\beta}_1 x_{n+1} \\ \text{Var}(y_{n+1} - \hat{y}_{n+1}) &= \text{Var}(y_{n+1}) + \text{Var}(\hat{y}_{n+1}) \\ &= \sigma^2 + \sigma^2 \left(\frac{1}{n} + \frac{(x - \bar{x})^2}{n \text{Var}(x)} \right) \\ &= \sigma^2 \left(\textcolor{red}{1} + \frac{1}{n} + \frac{(x - \bar{x})^2}{n \text{Var}(x)} \right) \\ \implies y_{n+1} - \hat{y}_{n+1} &\sim N\left(0, \sigma^2 \left(\textcolor{red}{1} + \frac{1}{n} + \frac{(x - \bar{x})^2}{n \text{Var}(x)} \right)\right) \\ \implies \frac{y_{n+1} - \hat{y}_{n+1} - 0}{\hat{\sigma} \sqrt{1 + \frac{1}{n} + \frac{(x_{n+1} - \bar{x})^2}{n \text{Var}(x)}}} &\sim t_{n-2} \\ \implies \mathbb{P} \left[y_{n+1} \in \hat{y}_{n+1} \pm t_{n-2}(0.025) \hat{\sigma} \sqrt{1 + \frac{1}{n} + \frac{(x - \bar{x})^2}{n \text{Var}(x)}} \right] &= 0.95\end{aligned}$$

Bayesian statistics

Bayes Rule:

$$f_{Y|X}(y | x) = \frac{f_{X,Y}(x, y)}{f_X(x)} = \frac{f_{X|Y}(x | y) \cdot f_Y(y)}{f_X(x)}$$

Posterior Probability:

$$f_{\Theta|X}(\theta | x) = \frac{f_{X|\Theta}(x | \theta) f_{\Theta}(\theta)}{f_X(x)}$$

where $f_{\Theta|X}(\theta | x)$ is the **posterior probability**, $f_{\Theta}(\theta)$ is the **prior probability**, $f_{X|\Theta}(x | \theta)$ is the **likelihood density**, and $f_X(x)$ is a normalizing constant.

$$f_{\Theta|X}(\theta | x) \propto f_{X|\Theta}(x | \theta) f_{\Theta}(\theta)$$

- We treat the parameter θ as a random variable in Bayesian statistics, when the frequentists treat the parameter as some fixed constant.
- An estimate of θ is called the **posterior mean** $\hat{\theta} = \mathbb{E}(\Theta | X)$, which is a function of X .
- When the prior and posterior distributions belong to the same distribution family, we say that the **prior and likelihood are conjugate**.

Bayesian statistics

Example : Beta distribution $X \sim \text{Beta}(\gamma, s)$

$$f(x) = \frac{\Gamma(\gamma + s)}{\Gamma(\gamma)\Gamma(s)} x^{\gamma-1} (1-x)^{s-1}, \mathbb{E}(x) = \frac{\gamma}{\gamma + s}$$

For instance, denote the prior as $p \sim \text{Beta}(\gamma, s)$, and the likelihood density is $X \mid p \sim \text{Binomial}(n, p)$. Then, the posterior is $p \mid X = x \sim \text{Beta}(x + \gamma, n - x + s)$, and the posterior mean is $\hat{p} = \mathbb{E}(p \mid X = x) = \frac{x + \gamma}{n + \gamma + s}$.

Problem 1: Bayesian Statistics

Consider a biased coin with probability of landing heads equal to θ . Also, let X be a random variable that is equal to 1 when the coin lands heads, and is otherwise equal to 0. In other words, we assume that $P(X = 1|\Theta = \theta) = \theta$, while $P(X = 0|\Theta = \theta) = 1 - \theta$. We consider the following prior for Θ :

$$f_{\Theta}(\theta) = \begin{cases} \theta e^{\theta} & \text{for } 0 \leq \theta \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

- (a) Find the probability that a coin toss results in heads: i.e., compute $P(X = 1)$.
- (b) Given that a coin toss results in heads, find the posterior density for Θ .
- (c) Given that the first toss resulted in heads, find the conditional probability of heads on the second toss. (*Hint*: this is tricky. Use the posterior from part (b) as the new prior!)

Problem 2: Posterior Mean

Let's assume the same setup from problem 2 above but turn to the Bayesian perspective with the flat prior $\Theta \sim \text{Unif}(0, 1)$.

Find the posterior distribution of $\Theta|X_1, \dots, X_n$.

Show that the posterior mean $E(\Theta|X_1, \dots, X_n)$ is a weighted average of $\hat{\Theta}_{ML}$ from problem 2 and the prior mean.

Problem 3: MLE, MoM

Suppose that we have n i.i.d random variables X_1, X_2, \dots, X_n , each with the following probability function (as usual, $0 \leq \theta \leq 1$ is unknown):

$$P(X = 0|\theta) = \frac{2}{3}\theta, \quad P(X = 1|\theta) = \frac{1}{3}\theta, \quad P(X = 2|\theta) = \frac{2}{3}(1-\theta), \quad P(X = 3|\theta) = \frac{1}{3}(1-\theta)$$

- (a) Find $\hat{\theta}_{\text{ML}}$, i.e. the max likelihood estimate of θ . Also find $E(\hat{\theta}_{\text{ML}})$ and $\text{Var}(\hat{\theta}_{\text{ML}})$.
- (b) Find $\hat{\theta}_{\text{MM}}$, i.e. the method of moments estimate of θ (it will depend only on $\hat{\mu}_1 = \bar{X}$)
- (c) Compute the standard error of $\hat{\theta}_{\text{MM}}$. Note that it is a function of θ .
- (d) How does the standard error of $\sigma_{\hat{\theta}_{\text{MM}}}$ compare to the standard error of $\sigma_{\hat{\theta}_{\text{ML}}}$ for different values of θ ? *Hint:* It is in fact a bit simpler to compare their squares.
- (e) Finally, assume that we have a sample $x = (3, 0, 2, 1, 3, 2, 1, 0, 2, 1)$, compute (i): the MLE $\hat{\theta}_{\text{ML}}$ (it is a number!) and its *estimated* standard error; and (ii): the MOM $\hat{\theta}_{\text{MM}}$ and its estimated standard error.
